## Optic Canal Narrowing in Hunter Syndrome (Mucopolysaccharidosis II)

I read with interest the article “Brain and Spinal MR Imaging Findings in Mucopolysaccharidoses: A Review”<sup>1</sup> and would like to illustrate optic canal narrowing in a patient with Hunter syndrome (mucopolysaccharidosis [MPS]-II).

A 6-year-old boy presented with significant loss of vision. He had been evaluated (at 3 years of age) for mucopolysaccharidosis; clinical phenotype, heparin sulfate in urine electrophoresis, and plasma enzyme levels (iduronate 2-sulfatase level: 4.2 nmol/h by fluorimetric assay by using 4-methyl umbelliferone; normal range: 167–475 nmol/h; control: 194.3) were suggestive of Hunter syndrome.

MR imaging of the brain showed periventricular white matter hyperintensities (Fig 1A–C), enlarged Virchow-Robin spaces (Fig 1A, -B), ventriculomegaly, and atrophy (Fig 1A–C, -E, -F), known features of mucopolysaccharidosis. The bilateral optic canals were symmetrically narrowed (Fig 1D–F), and hyperintensities were noted around both optic nerves (Fig 1C–F).

Hunter syndrome, or mucopolysaccharidosis II, is an X-linked progressive lysosomal storage disease due to deficiency of the lysosomal enzyme iduronate-2-sulfatase. Known ocular manifestations of Hunter syndrome include exophthalmos, hypertelorism, pigmentary retinopathy, uveal effusion, optic nerve

head swelling (disc edema,<sup>2</sup> possibly due to compression by scleral deposits), and optic atrophy.

Optic canal narrowing is a known feature of osteopetrosis,<sup>3</sup> and fibrous dysplasia and has been described in familial hypophosphatemic rickets, carbonic anhydrase type 2 deficiency (which includes osteopetrosis), and MPS-4.<sup>4</sup> It has not been previously reported in Hunter syndrome. Perhaps optic canal narrowing is underdiagnosed in Hunter syndrome because intellectually impaired children may not be able to describe visual loss.
