Computed Tomography of the Brain Stem with Intrathecal Metrizamide.

Part I: The Normal Brain Stem

Michel E. Mawad¹
A. John Silver
Sadek K. Hital
S. Ramaiah Ganti

Detailed anatomy of the brain stem and cervicomedullary junction demonstrated with metrizamide computed tomographic surface anatomy is unusually well outlined. Nine distinct anatomic levels are described: four levels in the medulla, three in the pons, and two in the midbrain. Surface features of the brain stem, fourth ventricle, cranial nerves, and vascular structures are

reliably accurate imaging of the brain stem and cervicomedullary junction now become available using high-resolution computed tomography following intrathecal administration of metrizamide. The surface features of the brain stem such as the vermis, sulcus, pyramids, and olivary protuberance has been demonstrated. Details have not been routinely demonstrable in the past.

Many authors [1, 2] have already emphasized the value of computed tomography and its superiority to both angiography and myelography. These latter procedures rely on subtle displacement of the air-filled fourth ventricle and posterior fossa. Metrizamide spreads much more readily in the subarachnoid space without the problem of meniscus formation or "air" loculation of the various collections of contrast agent and a variety of features encountered in nontomographic contrast studies.

Improved visualization of the details of the brain stem allowed the detection of subtle morphologic change, subarachnoid space not previously appreciated. Distortions of the various vessels, focal atrophic changes, and early changes in the brain stem, cerebellum, and fourth ventricle on CT cisternography is essential in order to fully utilize the diagnostic capability of metrizamide CT.

Materials and Methods

From those patients who were referred to our institution in an 18 month period, the brain stem in 30 who had metrizamide was studied.

Metrizamide was introduced more often through a C1-C2 approach. The average amount of contrast agent was 10 ml.

Dyke Postmortem CT and Autopsy in Perinatal Intracranial Hemorrhage

B. Ludwig¹
K. Becker²
G. Rutter³
J. Bohl⁴
M. Brand⁵

To improve interpretation of intracranial computed tomographic findings in vivo, postmortem computed tomography was correlated directly with autopsy findings in 105 specimens of human stillborn and live-born infants, ranging in age from gestational week 13 to postnatal month 18. This study identifies the typical computed tomographic appearance of intracranial and other hemorrhages, attempts to correlate the type of hemorrhage with brain maturity, and documents that postmortem computed tomography is useful to the neuropathologist as a supplementary method complementing the traditional postmortem examination.

In recent years, computed tomography (CT) and sonography of newborns have greatly improved our understanding of neonatal intracranial hemorrhage [1-10]. New insights into in vivo morphology of these lesions [11-15] have made it possible to predict the control of a morphologic diagnostic procedure. Pathologic confirmation of its accuracy, the correlation of CT and postmortem pathology [16-20].

Postmortem CT provides a unique method for detecting and characterizing intracranial pathology. (1) CT findings and pathology can be directly compared. (2) The progression of pathology in the highly variable brain can be studied. (3) The state of the brain at postmortem examination can be determined. (4) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (5) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (6) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (7) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (8) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (9) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (10) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (11) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (12) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (13) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (14) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (15) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (16) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (17) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (18) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (19) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (20) CT can be used to determine intracranial changes in information about these changes in the postmortem examination.

(16) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (17) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (18) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (19) CT can be used to determine intracranial changes in information about these changes in the postmortem examination. (20) CT can be used to determine intracranial changes in information about these changes in the postmortem examination.

Since 1980, CT has been performed after autopsy in the Department of Neurology. We have tried to delineate some aspects of the correlation between postmortem CT and autopsy. Preliminary results are presented.
